

# 具有智能电流限制的 LM34917A 超小型 33V, 1.25A 恒定接通时间降压开关稳压器

 查询样品: [LM34917A](#)

## 特性

- 工作输入电压范围: **8V 至 33V**
- 芯片尺寸球栅阵列 (DSBGA) 封装
- $\approx 35V$  时, 输入过压关断
- 瞬态能力达到 **50V**
- 集成 **N** 通道降压开关
- 随  $V_{IN}$  和  $V_{OUT}$  变化的谷值电流限值以减少过多电感器电流
- 电流限制时, 接通时间被减少
- 集成启动稳压器
- 无需环路补偿
- 超快瞬态响应
- 最大开关频率: **2MHz**
- 在负载电流和输入电压变化时, 工作频率几乎保持恒定
- 可编程软启动
- 精密内部基准
- 可调输出电压
- 热关断

## 典型应用

- 高效负载点 (POL) 稳压器
- 非隔离式降压稳压器
- 次级高压后置稳压器

## 基本降压稳压器

## 封装

- **12** 焊锡凸点 **DSBGA** 封装

## 说明

LM34917A 降压开关稳压器特有执行低成本、高效降压偏置稳压器 (至少能够为负载提供 1.25A 的电流) 所需的全部功能。为了减少由可能的电感器饱和和所导致的过多开关电流, 谷值电流限值阈值随着输入和输出电压的变化而改变, 而且接通时间会在检测到电流限值时被减少。这个降压稳压器包含一个 **N** 通道降压开关并且采用 12 引脚 **DSBGA** 封装。恒定接通时间反馈调节机制无需环路补偿, 从而实现快速负载瞬态响应, 并简化电路实现。由于输入电压和接通时间之间的反比关系, 线路和负载变化时, 运行频率保持恒定。谷值电流限制可在检测到电流限值时实现恒定电压到恒定电流的平滑转换, 从而在不使用折返的情况下减少频率和输出电压。额外特性包括:  $V_{CC}$  欠压闭锁、输入过压关断、热关断、栅极驱动欠压闭锁和最大占空比限制。

## 引脚说明

引脚 编号	名称	说明	应用信息
A1	SGND	感测接地	再循环电流从这个引脚流入电流感测电阻器。
A2	RTN	电路接地	针对除电流限值检测之外所有内部电路的接地。
A3	FB	反馈输入来自经稳压输出	被内部连接至稳压和过压比较器。此稳压电平为 2.5V。
B1	ISEN	电流感测	再循环电流从这个引脚流入续流二极管。
B2	RON/SD	接通时间控制和关断	VIN 和这个引脚之间的一个外部电阻器设定降压开关接通时间。把这个引脚接地将关断稳压器。
B3	SS	软启动	一个内部电流源将外部电容器充电至 2.5V，从而提供软启动功能。
C1, C2	VIN	输入电源电压	工作输入电压范围为 8.0V 至 33V，此时过压关断在内部设定为 $\approx 35V$ 。瞬态能力为 50V。
C3	VCC	启动稳压器的输出	标称稳压值为 7.0V。将一个 0.1 $\mu F$ 电容器由这个引脚连接至 RTN。可将一个外部电压 (8V 至 14V) 施加到这个引脚来减少内部耗散。将一个内部二极管连接在 VCC 和 VIN 之间。
D1, D2	SW	开关节点	内部连接至降压开关源。连接至电感器、二极管和引导电容器。
D3	BST	针对引导电容器的升压引脚	将一个 0.022 $\mu F$ 电容器由 SW 连接至这个引脚。每次关闭时间时，通过一个内部二极管对此电容器充电。

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

**Absolute Maximum Ratings<sup>(1)(2)</sup>**

VIN to RTN	50V
BST to RTN	64V
SW to RTN (Steady State)	-1.5V
BST to VCC	50V
VIN to SW	50V
BST to SW	14V
VCC to RTN	14V
SGND to RTN	-0.3V to +0.3V
Current out of ISEN	See text
SS to RTN	-0.3V to 4V
All Other Inputs to RTN	-0.3 to 7V
ESD Rating <sup>(3)</sup>	
Human Body Model	2kV
Storage Temperature Range	-65°C to +150°C
Junction Temperature	150°C

- (1) Absolute Maximum Ratings are limits beyond which damage to the device may occur. Operating Ratings are conditions under which operation of the device is intended to be functional. For specifications and test conditions, see the Electrical Characteristics.
- (2) If Military/Aerospace specified devices are required, please contact the TI Sales Office/Distributors for availability and specifications.
- (3) The human body model is a 100pF capacitor discharged through a 1.5kΩ resistor into each pin.

**Operating Ratings<sup>(1)</sup>**

VIN Voltage	8.0V to 33V
Junction Temperature	-40°C to + 125°C

- (1) Absolute Maximum Ratings are limits beyond which damage to the device may occur. Operating Ratings are conditions under which operation of the device is intended to be functional. For specifications and test conditions, see the Electrical Characteristics.

**Electrical Characteristics**

Limits in standard type are for  $T_J = 25^\circ\text{C}$  only; limits in **boldface** type apply over the junction temperature ( $T_J$ ) range of  $-40^\circ\text{C}$  to  $+125^\circ\text{C}$ . Minimum and Maximum limits are specified through test, design, or statistical correlation. Typical values represent the most likely parametric norm at  $T_J = 25^\circ\text{C}$ , and are provided for reference purposes only. Unless otherwise stated the following conditions apply:  $V_{IN} = 12\text{V}$ ,  $R_{ON} = 200\text{k}\Omega$ . See <sup>(1)</sup> and <sup>(2)</sup>.

## FUNCTIONAL DESCRIPTION

The LM34917A Step Down Switching Regulator features all the functions needed to implement a low cost, efficient buck power converter capable of supplying at least 1.25A to the load. This high voltage regulator contains an N-Channel buck switch, is easy to implement, and is available in the DSBGA package. The regulator's operation is based on a constant on-time control scheme where the on-time is inversely proportional to the input voltage. This feature results in the operating frequency remaining relatively constant with load and input voltage variations. The feedback control scheme requires no loop compensation resulting in very fast load transient response. The valley current limit scheme protects against excessively high currents if the output is short circuited when  $V_{IN}$  is high. To aid in controlling excessive switch current due to a possible saturating inductor the valley current limit threshold changes with input and output voltages, and the on-time is reduced by approximately 50% when current limit is detected. An over-voltage detection at  $V_{IN}$  stops the circuit's switching when the input voltage exceeds 34.8V. The LM34917A can be applied in numerous applications to efficiently regulate down higher voltages. Additional features include: Thermal shutdown,  $V_{CC}$  under-voltage lock-out, gate drive under-voltage lock-out, and maximum duty cycle limit.

### Control Circuit Overview

The LM34917A buck DC-DC regulator employs a control scheme based on a comparator and a one-shot on-timer, with the output voltage feedback (FB) compared to an internal reference (2.5V). If the FB voltage is below the reference the buck switch is switched on for a time period determined by the input voltage and a programming resistor ( $R_{ON}$ ). Following the on-time the switch remains off until the FB voltage falls below the reference, but for a time not less than the minimum off-time forced by the LM34917A. The buck switch is then switched on for another on-time period.

When in regulation, the LM34917A operates in continuous conduction mode at heavy load currents and discontinuous conduction mode at light load currents. In continuous conduction mode the inductor's current is always greater than zero, and the operating frequency remains relatively constant with load and line variations. The minimum load current for continuous conduction mode is one-half the inductor's ripple current amplitude. The approximate operating frequency is calculated as follows:

$$f_{SW} = \frac{V_{OUT} \times (V_{IN} - 1.35V)}{V_{IN} \times 1.16 \times 10^{-10} \times (R_{ON} + 1.4k)} \quad (1)$$

The buck switch duty cycle is equal to:

$$DC = \frac{t_{ON}}{t_{ON} + t_{OFF}} = t_{ON} \times f_{SW} = \frac{V_{OUT}}{V_{IN}} \quad (2)$$

In discontinuous conduction mode, where the inductor's current reaches zero during the off-time forcing a longer-than-normal off-time, the operating frequency is lower than in continuous conduction mode, and varies with load current. Conversion efficiency is maintained at light loads since the switching losses reduce with the reduction in load and frequency. The approximate discontinuous operating frequency can be calculated as follows:

$$f_{SW} = \frac{V_{OUT}^2 \times L1 \times 1.48 \times 10^{20}}{R_L \times R_{ON}^2} \quad (3)$$

where  $R_L$  = the load resistance, and  $L1$  is the circuit's inductor.

The output voltage is set by the two feedback resistors ( $R1$ ,  $R2$  in the Block Diagram). The regulated output voltage is calculated as follows:

$$V_{OUT} = 2.5 \times (R1 + R2) / R2 \quad (4)$$

Output voltage regulation is based on supplying ripple voltage to the feedback input (FB pin) in phase with the SW pin. The LM34917A requires a minimum of 25 mVp-p of ripple voltage at the FB pin. The ripple is generated as a triangle waveform at the junction of  $R3$  and  $C8$  as the SW pin switches high and low, and fed to the FB pin by  $C7$ .

If the voltage at FB rises above 2.9V, due to a transient at  $V_{OUT}$  or excessive inductor current which creates higher than normal ripple at  $V_{OUT}$ , the internal over-voltage comparator immediately shuts off the internal buck switch. The next on-time starts when the voltage at FB falls below 2.5V and the inductor current falls below the current limits threshold.

## ON-Time Timer

The on-time for the LM34917A is determined by the  $R_{ON}$  resistor and the input voltage ( $V_{IN}$ ), calculated from:

$$t_{ON} = \frac{1.16 \times 10^{-10} \times (R_{ON} + 1.4 \text{ k}\Omega)}{V_{IN} - 1.35\text{V}} + 100 \text{ ns} \quad (5)$$

The inverse relationship with  $V_{IN}$  results in a nearly constant frequency as  $V_{IN}$  is varied. To set a specific continuous conduction mode switching frequency ( $f_{SW}$ ), the  $R_{ON}$  resistor is determined from the following:

$$R_{ON} = \frac{V_{OUT} \times (V_{IN} - 1.35\text{V})}{V_{IN} \times 1.16 \times 10^{-10} \times f_{SW}} - 1.4\text{k}\Omega \quad (6)$$

Equation 1, Equation 5 and Equation 6 are valid only during normal operation - i.e., the circuit is not in current limit. When the LM34917A operates in current limit, the on-time is reduced by approximately 50%. This feature reduces the peak inductor current which may be excessively high if the load current and the input voltage are simultaneously high. This feature operates on a cycle-by-cycle basis until the load current is reduced and the output voltage resumes its normal regulated value. Equation 1, Equation 5 and Equation 6 have a  $\pm 25\%$  tolerance.

## Remote Shutdown

The LM34917A can be remotely shut down by taking the  $R_{ON}/SD$  pin below 0.65V. See Figure 13. In this mode the SS pin is internally grounded, the on-timer is disabled, and bias currents are reduced. Releasing the  $R_{ON}/SD$  pin allows the circuit to resume operation after the SS pin voltage is below 0.18V. The voltage at the  $R_{ON}/SD$  pin is normally between 1.4V and 3.5V, depending on  $V_{IN}$  and the  $R_{ON}$  resistor.

Figure 13. Remote Shutdown

## Input Over-Voltage Shutdown

If the input voltage at  $V_{IN}$  increases above 34.8V an internal comparator disables the buck switch and the on-timer, and grounds the soft-start pin. Normal operation resumes when the  $V_{IN}$  voltage reduces below 34.8V, and when the soft-start voltage (at the SS pin) has reduced below 0.18V.

## Current Limit

Current limit detection occurs during the off-time by monitoring the recirculating current flowing out of the ISEN pin. Referring to the Block Diagram, during the off-time the inductor current flows through the load, into SGND, through the internal sense resistor, out of ISEN and through D1 to the inductor. If that current exceeds the current limit threshold the current limit comparator output delays the start of the next on-time period. The next on-time starts when the current out of ISEN is below the threshold **and** the voltage at FB falls below 2.5V. The operating frequency is typically lower due to longer-than-normal off-times.

The valley current limit threshold is a function of the input voltage ( $V_{IN}$ ) and the output voltage sensed at FB, as shown in the graph "Valley Current Limit Threshold vs.  $V_{FB}$  and  $V_{IN}$ ". This feature reduces the inductor current's peak value at high line and load. To further reduce the inductor's peak current, the next cycle's on-time is reduced by approximately 50% if the voltage at FB is below its threshold when the inductor current reduces to the current limit threshold ( $V_{OUT}$  is low due to current limiting).

Figure 14 illustrates the inductor current waveform during normal operation and in current limit. During the first “Normal Operation” the load current is  $I_{OUT1}$ , the average of the ripple waveform. As the load resistance is reduced, the inductor current increases until it exceeds the current limit threshold. During the “Current Limited” portion of Figure 14, the current limit threshold lowers since the high load current causes  $V_{OUT}$  (and the voltage at FB) to reduce. The on-time is reduced by approximately 50%, resulting in lower ripple amplitude for the inductor’s current. During this time the LM34917A is in a constant current mode, with an average load current equal to the current limit threshold +  $\Delta I/2$  ( $I_{OUT2}$ ). Normal operation resumes when the load current is reduced to  $I_{OUT3}$ , allowing  $V_{OUT}$ , the current limit threshold, and the on-time to return to their normal values. Note that in the second period of “Normal Operation”, even though the inductor’s peak current exceeds the current limit threshold during part of each cycle, the circuit is not in current limit since the current falls below the threshold before the feedback voltage reduces to its threshold to initiate the next on-time.

The peak current allowed through the buck switch, and the ISEN pin, is 2A, and the maximum allowed average current is 1.5A.

Figure 14. Inductor Current - Normal and Current Limit Operation

## N - Channel Buck Switch and Driver

The LM34917A integrates an N-Channel buck switch and associated floating high voltage gate driver. The gate driver circuit works in conjunction with an external bootstrap capacitor and an internal high voltage diode. A 0.022  $\mu\text{F}$  capacitor (C4) connected between BST and SW provides the voltage to the driver during the on-time. During each off-time, the SW pin is at approximately -1V, and C4 is recharged for the next on-time from  $V_{CC}$  through the internal diode. The minimum off-time ensures a minimum time each cycle to recharge the bootstrap capacitor.

## Softstart

The softstart feature allows the converter to gradually reach a steady state operating point, thereby reducing start-up stresses and current surges. Upon turn-on, after  $V_{CC}$  reaches the under-voltage threshold, an internal 11.6  $\mu\text{A}$  current source charges up the external capacitor at the SS pin to 2.5V ( $t_2$  in Figure 12). The ramping voltage at SS (and the non-inverting input of the regulation comparator) ramps up the output voltage in a controlled manner.

An internal switch grounds the SS pin if  $V_{CC}$  is below the under-voltage lockout threshold, if the RON/SD pin is grounded, or if  $V_{IN}$  exceeds the overvoltage threshold.

## Thermal Shutdown

The LM34917A should be operated so the junction temperature does not exceed 125°C. If the junction temperature increases above that, an internal Thermal Shutdown circuit activates (typically) at 175°C, taking the controller to a low power reset state by disabling the buck switch. This feature helps prevent catastrophic failures from accidental device overheating. When the junction temperature reduces below 155°C (typical hysteresis = 20°C), normal operation resumes.

## Applications Information

### EXTERNAL COMPONENTS

The procedure for calculating the external components is illustrated with the following design example. Referring to the Block Diagram, the circuit is to be configured for the following specifications:

- $V_{OUT} = 5V$
- $V_{IN} = 8V$  to 33V
- Minimum load current = 200 mA
- Maximum load current = 1000 mA
- Switching Frequency = 1.5 MHz
- Soft-start time = 5 ms
- Output voltage ripple level: Minimum

**R1 and R2:** These resistors set the output voltage. The ratio of the feedback resistors is calculated from:

$$R1/R2 = (V_{OUT}/2.5V) - 1 \quad (7)$$

For this example,  $R1/R2 = 1$ . R1 and R2 should be chosen from standard value resistors in the range of 1.0 k $\Omega$  – 10 k $\Omega$  which satisfy the above ratio. For this example, 2.49 k $\Omega$  is chosen for R1 and R2.

**R<sub>ON</sub>:** This resistor sets the on-time, and (by default) the switching frequency. Since the maximum frequency is limited by the minimum off-time forced by the LM34917A, first check that the desired frequency is less than:

$$f_{SW} < \frac{V_{IN} - V_{OUT}}{V_{IN} \times 105 \text{ ns}} = 3.57 \text{ MHz at } V_{IN} = 8V \quad (8)$$

The R<sub>ON</sub> resistor is calculated from [Equation 6](#) using the minimum input voltage:

$$R_{ON} = \frac{V_{OUT} \times (V_{IN(min)} - 1.35V)}{V_{IN(min)} \times 1.16 \times 10^{-10} \times f_{SW}} - 1.4 \text{ k}\Omega = 22.49 \text{ k}\Omega \quad (9)$$

[Equation 5](#) is used to verify that this value resistor does not set an on-time less than 120 ns at maximum input voltage. A standard value 22.1 k $\Omega$  resistor is used, resulting in a nominal frequency of 1.49 MHz. The minimum on-time is 188 ns at  $V_{in} = 33V$ , and the maximum on-time is 510 ns at  $V_{in} = 8V$ .

**L1:** The main parameter affected by the inductor is the inductor current ripple amplitude ( $I_{OR}$ ). The minimum load current is used to determine the maximum allowable ripple in order to maintain continuous conduction mode, where the lower peak does not reach 0 mA. This is not a requirement of the LM34917A, but serves as a guideline for selecting L1. For this example, the maximum ripple current should be less than:

$$I_{OR(MAX)} = 2 \times I_{OUT(min)} = 400 \text{ mAp-p} \quad (10)$$

For other applications, if the minimum load current is zero, use 20% of  $I_{OUT(max)}$  for  $I_{OUT(min)}$  in [Equation 10](#). The ripple amplitude calculated in [Equation 10](#) is then used in the following equation:

$$L1_{(min)} = \frac{t_{on(min)} \times (V_{IN(max)} - V_{OUT})}{I_{OR(max)}} = 13.2 \mu\text{H} \quad (11)$$

A standard value 15  $\mu\text{H}$  inductor is selected. The maximum ripple amplitude, which occurs at maximum  $V_{IN}$ , calculates to 351 mA p-p, and the peak current is 1175 mA at maximum load current. Ensure the selected inductor is rated for this peak current.

**C2:** C2 should typically be no smaller than 3.3  $\mu\text{F}$ , although that is dependent on the frequency and the desired output characteristics. C2 should be a low ESR good quality ceramic capacitor. Experimentation is usually necessary to determine the minimum value for C2, as the nature of the load may require a larger value. A load which creates significant transients requires a larger value for C2 than a non-varying load.

**C1 and C5:** C1's purpose is to supply most of the switch current during the on-time, and limit the voltage ripple at  $V_{IN}$ , since it is assumed the voltage source feeding  $V_{IN}$  has some amount of source impedance.

At maximum load current, when the buck switch turns on, the current into  $V_{IN}$  suddenly increases to the lower peak of the inductor's ripple current, ramps up to the upper peak, then drops to zero at turn-off. The average current during the on-time is the load current. For a worst case calculation, C1 must supply this average load current during the maximum on-time, without letting the voltage at  $V_{IN}$  drop below  $\approx 7.5V$ . The minimum value for C1 is calculated from:

$$C1 = \frac{I_{OUT(max)} \times t_{ON}}{\Delta V} = 1.02 \mu F \quad (12)$$

where  $t_{ON}$  is the maximum on-time, and  $\Delta V$  is the allowable ripple voltage at  $V_{IN}$  (0.5V at  $V_{IN} = 8V$ ). C5's purpose is to minimize transients and ringing due to long lead inductance leading the  $V_{IN}$  pin. A low ESR 0.1  $\mu F$  ceramic chip capacitor must be located close to the  $V_{IN}$  and  $RTN$  pins.

**C3:** The capacitor at the  $VCC$  pin provides noise filtering and stability for the  $VCC$  regulator. C3 should be no smaller than 0.1  $\mu F$ , and should be a good quality, low ESR ceramic capacitor. C3's value, and the  $VCC$  current limit, determine a portion of the turn-on-time ( $t_1$  in [Figure 12](#)).

**C4:** The recommended value for C4 is 0.022  $\mu F$ . A high quality ceramic capacitor with low ESR is recommended as C4 supplies a surge current to charge the buck switch gate at each turn-on. A low ESR also helps ensure a complete recharge during each off-time.

**C6:** The capacitor at the  $SS$  pin determines the soft-start time, i.e. the time for the output voltage to reach its final value ( $t_2$  in [Figure 12](#)). The capacitor value is determined from:

$$C6 = \frac{t_2 \times 11.6 \mu A}{2.5V} = 0.023 \mu F \quad (13)$$

**R3, C7, C8:** The ripple amplitude at  $V_{OUT}$  is determined by C2's characteristics and the inductor's ripple current amplitude, and typically ranges from 5 mV to 30 mV over the  $V_{in}$  range. Since the LM34917A's regulation comparator requires a minimum of 25 mVp-p ripple at the  $FB$  pin, these three components are added to generate and provide the necessary ripple to  $FB$  in phase with the waveform at  $SW$ . R3 and C8 are chosen to generate a sawtooth waveform at their junction, and that voltage is AC coupled to the  $FB$  pin via C7. To determine the values for R3, C7 and C8, the following procedure is used:

$$\text{Calculate } V_A = V_{OUT} - (V_{SW} \times (1 - (V_{OUT}/V_{IN(min)}))) \quad (14)$$

where  $V_{SW}$  is the absolute value of the voltage at the  $SW$  pin during the off-time (typically 1V).  $V_A$ , the DC voltage at the R3/C8 junction, calculates to 4.63V, and is used in the next equation.

$$R3 \times C8 = \frac{(V_{IN(min)} - V_A) \times t_{ON}}{\Delta V} = 17.5 \times 10^{-6} \quad (15)$$

where  $t_{ON}$  is the maximum on-time (at minimum input voltage), and  $\Delta V$  is the desired ripple amplitude at the R3/C8 junction, typically 100 mV. R3 and C8 are chosen from standard value components to satisfy the above product. For this example, 3300 pF is chosen for C8, and 5.23 k $\Omega$  is chosen for R3. C7 is chosen large compared to C8, typically 0.1  $\mu F$ .

**D1:** A Schottky diode is recommended. Ultra-fast recovery diodes are not recommended as the high speed transitions at the  $SW$  pin may inadvertently affect the IC's operation through external or internal EMI. The diode must be rated for the maximum input voltage, the maximum load current, and the peak current which occurs when the current limit and maximum ripple current are reached simultaneously. The diode's average power dissipation is calculated from:

$$P_{D1} = V_F \times I_{OUT} \times (1-D) \quad (16)$$

where  $V_F$  is the diode's forward voltage drop, and  $D$  is the on-time duty cycle.

## FINAL CIRCUIT

The final circuit is shown in [Figure 15](#), and its performance is shown in [Figure 16](#) and [Figure 17](#). Current limit measured approximately 1.34A at  $V_{in} = 8V$ , and 1.27A at  $V_{in} = 33V$ . The output ripple amplitude measured 4 mVp-p at  $V_{in} = 8V$ , and 14 mVp-p at  $V_{in} = 33V$ .

Figure 17. Frequency vs. VIN (Circuit of Figure 15)

**ALTERNATE OUTPUT RIPPLE CONFIGURATIONS**

For applications which can accept higher levels of ripple at VOUT, the following configurations are simpler and a bit more economical.

**a) Alternate #1:** In Figure 18, R3, C7 and C8 are removed, and Cff and R4 are installed, resulting in a higher ripple level than the circuit of Figure 15. Ripple is created at VOUT by the inductor’s ripple current passing through R4. That ripple voltage is AC coupled to the FB pin through Cff, allowing the minimum ripple at VOUT to be set at 25 mVp-p. The minimum ripple current amplitude (IOR(min)) is calculated by re-arranging Equation 11 using tON(max) and VIN(min). The minimum value for R4 is calculated from:

$$R4 = \frac{25 \text{ mV}}{I_{OR(\text{min})}} \tag{17}$$

The next larger standard value resistor should be selected for R4 to allow for tolerances. The minimum value for Cff is determined from:

$$C_{ff} = \frac{t_{ON(max)}}{(R1 // R2)} \quad (18)$$

The next larger standard value capacitor should be used for Cff.

Figure 18. Reduced Ripple Configuration

**b) Alternate #2:** In Figure 19, R3, C7 and C8 are removed, and R4 is installed, resulting in a higher ripple level than the circuits of Figure 15 and Figure 18. Ripple is created at V<sub>OUT</sub> by the inductor's ripple current passing through R4. That ripple voltage is coupled to the FB pin through the feedback resistors (R1, R2). Since the LM34917A requires a minimum of 25 mVp-p ripple at the FB pin, the ripple required at V<sub>OUT</sub> is higher than 25 mVp-p by the gain of the feedback resistors. The minimum ripple current (I<sub>OR(min)</sub>) is calculated by re-arranging Equation 11 using t<sub>ON(max)</sub> and V<sub>IN(min)</sub>. The minimum value for R4 is calculated from:

$$R4_{(min)} = \frac{25 \text{ mV} \times (R1 + R2)}{R2 \times I_{OR(min)}} \quad (19)$$

The next larger standard value resistor should be used for R4.

Figure 19. Maximum Ripple Configuration

**c) Alternate minimum ripple configuration:** The circuit in Figure 20 is the same as that in Figure 19, except the output voltage is taken from the junction of R4 and C2. The ripple at V<sub>OUT</sub> is determined by the inductor's ripple current and C2's characteristics. However, R4 slightly degrades the load regulation. This circuit may be suitable if the load current is fairly constant. R4 is calculated as described in Alternate #2 above.

**Figure 20. Alternate Minimum Output Ripple Configuration**

### Minimum Load Current

The LM34917A requires a minimum load current of 1 mA. If the load current falls below that level, the bootstrap capacitor (C4) may discharge during the long off-time, and the circuit will either shutdown, or cycle on and off at a low frequency. If the load current is expected to drop below 1 mA in the application, R1 and R2 should be chosen low enough in value so they provide the minimum required current at nominal  $V_{OUT}$ .

### PC BOARD LAYOUT

Refer to application note AN-1112 for PC board guidelines for the DSBGA package.

The LM34917A regulation, over-voltage, and current limit comparators are very fast, and respond to short duration noise pulses. Layout considerations are therefore critical for optimum performance. The layout must be as neat and compact as possible, and all of the components must be as close as possible to their associated pins. The two major current loops have currents which switch very fast, and so the loops should be as small as possible to minimize conducted and radiated EMI. The first loop is that formed by C1, through the VIN to SW pins, L1, C2, and back to C1. The second current loop is formed by D1, L1, C2 and the SGND and ISEN pins.

The power dissipation within the LM34917A can be approximated by determining the total conversion loss ( $P_{IN} - P_{OUT}$ ), and then subtracting the power losses in the free-wheeling diode and the inductor. The power loss in the diode is approximately:

$$P_{D1} = I_{out} \times V_F \times (1-D) \quad (20)$$

where  $I_{out}$  is the load current,  $V_F$  is the diode's forward voltage drop, and  $D$  is the on-time duty cycle. The power loss in the inductor is approximately:

$$P_{L1} = I_{out}^2 \times R_L \times 1.1 \quad (21)$$

where  $R_L$  is the inductor's DC resistance, and the 1.1 factor is an approximation for the AC losses. If it is expected that the internal dissipation of the LM34917A will produce excessive junction temperatures during normal operation, good use of the PC board's ground plane can help to dissipate heat. Additionally the use of wide PC board traces, where possible, can help conduct heat away from the IC. Judicious positioning of the PC board within the end product, along with the use of any available air flow (forced or natural convection) can help reduce the junction temperatures.

---

**REVISION HISTORY**

<b>Changes from Revision C (March 2013) to Revision D</b>	<b>Page</b>

**PACKAGING INFORMATION**

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
LM34917ATL/NOPB	ACTIVE	DSBGA	YZR	12	250	RoHS & Green	SNAGCU	Level-1-260C-UNLIM	-40 to 125	SRHA	Samples

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
